An Order Four Continuous Numerical Method for Solving General Second Order Ordinary Differential Equations

F. O. Obarhua*, O. J. Adegboro

Department of Mathematical Sciences, The Federal University of Technology, Akure, Nigeria

Abstract

Continuous hybrid methods are now recognized as efficient numerical methods for problems whose solutions have finite domains or cannot be solved analytically. In this work, the continuous hybrid numerical method for the solution of general second order initial value problems of ordinary differential equations is considered. The method of collocation of the differential system arising from the approximate solution to the problem is adopted using the power series as a basis function. The method is zero stable, consistent, convergent. It is suitable for both non-stiff and mildly-stiff problems and results were found to compete favorably with the existing methods in terms of accuracy.

DOI:10.46481/jnsps.2021.150

Keywords: Numerical Scheme, Continuous hybrid method, Zero stability, Linear and nonlinear

1. Introduction

We consider the second order Ordinary Differential Equation (ODEs)

\[ y'' = f(x, y, y'), \quad y(\mu) = \omega_0, \quad y'(\mu) = \omega_1 \]  \hspace{1cm} (1)

Equation (1) occur virtually every areas of physical or biological process in connection with numerous problems that are encountered in various aspects of everyday life. It is well conceived that this type of equation can either be solved directly or solved by reducing to system of first order differential equations before applying different methods available to solve the resulting system of first order ODEs Chan et al. [1], Golbabai and Arabshahi [6]. Among the first methods developed are first derivative methods that are implemented in predictor-corrector mode, and Taylor series expan-
sion are adopted to provide the starting values. The identified setbacks of the predictor-corrector methods are; they are very costly to implement and reduced order of accuracy of the predictors. Recently, authors have proposed different methods of higher order differential equations to improve on the existing setbacks. Such improved methods are Kayode and Adeyeye, [7, 8] and Kayode and Obarhua, [9, 10]. They independently proposed linear multistep methods of higher order of accuracies and same order of main predictors and the correctors and hence improved significantly the accuracies of the methods.

This work proposed an accurate continuous numerical hybrid method for direct solution of initial value problems of ODEs. The derived method is capable to handle stiff, mildly stiff, nonlinear and engineering problems modeled as a second order initial value problem of ODEs.

2. Derivation of the Method

We define the general power series approximation solution in the form

\[ y(x) = \sum_{j=0}^{(c+i)-1} a_j x^j \]  
\[ y'(x) = \sum_{j=1}^{(c+i)-1} j a_j x^{j-1} \]  
\[ y''(x) = \sum_{j=2}^{(c+i)-1} j(j-1) a_j x^{j-2} \]  
\[ f(x, y, y') = \sum_{j=2}^{(c+i)-1} j(j-1) a_j x^{j-2} \]  

Equation (2) is interpolated at \( x_{n+i} \), \( i = 2, \frac{3}{2} \) and (5) is collocated at \( x_{n+c} \), \( c = 0(1.3) \).

Therefore, interpolation and collocation equation at the selected grid and offstep points give rise to system of equations which can be express in matrix form

\[
\begin{pmatrix}
1 & x_{n+2h} & x_{n+2h}^2 & x_{n+2h}^3 & x_{n+2h}^4 & x_{n+2h}^5 \\
1 & x_{n+rh} & x_{n+rh}^2 & x_{n+rh}^3 & x_{n+rh}^4 & x_{n+rh}^5 \\
0 & 0 & 2 & 6x_n & 12x_n^2 & 20x_n^3 \\
0 & 0 & 2 & 6x_{n+h} & 12x_{n+h}^2 & 20x_{n+h}^3 \\
0 & 0 & 2 & 6x_{n+2h} & 12x_{n+2h}^2 & 20x_{n+2h}^3 \\
0 & 0 & 2 & 6x_{n+3h} & 12x_{n+3h}^2 & 20x_{n+3h}^3
\end{pmatrix}
\begin{pmatrix}
a_0 \\
a_1 \\
a_2 \\
a_3 \\
a_4 \\
a_5
\end{pmatrix}
= \begin{pmatrix}
y_{n+2} \\
y_{n+r} \\
y_{n+2} \\
y_{n+1+2} \\
y_{n+2} \\
y_{n+3}
\end{pmatrix}
\begin{pmatrix}
a_0 \\
a_1 \\
a_2 \\
a_3 \\
a_4 \\
a_5
\end{pmatrix}
\begin{pmatrix}
f_n \\
f_{n+1} \\
f_{n+2} \\
f_{n+3} \\
f_{n+4} \\
f_{n+5}
\end{pmatrix}
\]

Gaussian elimination method is then applied to solve equation (6) to obtain the unknown coefficients \( a_i \)'s which is then substituted into (2). Continuous system is obtained after some algebraic simplifications.

Applying transformation \( t = \frac{1}{h} (x - x_{n+k-1}) \), \( k = 3, t = (0, 1) \) in Obarhua [11], the continuous coefficients are obtained as follows

\[
\begin{align*}
\alpha_2 &= \left( \frac{-rh + th + 2h}{h(r - 2)} \right) \\
\alpha_r &= \frac{th}{h(r - 2)} \\
\beta_0 &= \frac{h^5}{360} \left( -3t^5 + 10t^3 + 8t + 3tr^4 - 24tr^3 + 62tr^2 - 56tr \right) \\
\beta_1 &= -\frac{h^5}{120} \left( -3t^5 - 5t^3 + 20t^3 - 72t + 3tr^4 - 19tr^3 + 22tr^2 + 44tr \right) \\
\beta_2 &= \frac{h^5}{120} \left( -3t^5 - 10t^3 + 10t^3 + 60t^2 + 48t + 3tr^4 \right) \\
&= \left( \frac{14t^3 + 2tr^2 + 4tr}{h^3} \right)
\end{align*}
\]

The first derivatives of equation (7) are

\[
\begin{align*}
\alpha'_2 &= -\frac{1}{(r - 2)} \\
\alpha'_r &= \frac{1}{(r - 2)} \\
\beta'_0 &= \frac{h^5}{360} \left( -15t^4 + 30t^2 + 3r^4 - 24r^3 + 62r^2 - 56r + 8 \right) \\
\beta'_1 &= -\frac{h^5}{120} \left( -15t^4 - 20t^3 + 60t^2 + 3r^4 - 19r^3 + 22r^2 + 44r - 72 \right) \\
\beta'_2 &= \frac{h^5}{120} \left( -15t^4 - 40t^3 + 30t^2 + 120t + 12t^3r^4 - 56r^3 + 8r^2 \right) \\
&= \left( \frac{+4r + 48}{h^3} \right)
\end{align*}
\]

Evaluating equation (7) and (8) at \( t = 1 \) yield the discrete order continuous numerical scheme

\[
\begin{align*}
y_{n+3} &= -\frac{1}{360(r - 2)} \left( -60h^2r^5 f_{n+2} - 360y_{n+2} - 630h^2 f_{n+2} \\
&= -30h^2 f_n - 3h^2 r^5 f_{n+3} + 9h^2 r^5 f_{n+2} - 9h^2 r^5 f_{n+1} + 3h^2 r^5 f_n \\
&+ 15h^2 r^4 f_{n+3} - 20h^2 r^4 f_{n+2} - 180h^2 r^3 f_{n+1} + 90h^2 r^3 f_{n+2} \\
&- 180h^2 r^2 f_n + 110h^2 r^3 f_{n+1} - 30h^2 r^2 f_{n+2} - 75h^2 r^2 f_{n+3} \\
&= -60h^2 f_{n+2} + 360ry_{n+2} + 291h^2 r f_{n+2} + 360y_{n+r} - 360h^2 f_{n+2} \\
&+ 38h^2 r f_{n+3} + 444h^2 r f_{n+1} + 127h^2 r_{f_n}
\end{align*}
\]
its first derivative is given as

\[ y_{n+3}' = \frac{1}{360h(r-2)} \left(9h^2r^3f_{n+2} + 9h^2r^3f_{n+1} + 3h^2r^3f_n + 90h^2r^3f_{n+2} \right. \]
\[ - 60h^2r^3f_{n+2} + 110h^2r^3f_{n+1} - 180h^2r^2f_n - 30h^2r^3f_{n+1} - 180h^2r^2f_n \]
\[ - 30h^2r^2f_n + 75h^2r^3f_{n+1} - 20h^2r^2f_{n+1} \]
\[ + 15h^2r^4f_{n+3} - 254h^2f_{n+3} - 858h^2f_{n+2} - 282h^2f_{n+1} \]
\[ - 46h^2f_n + 360y_{n+2} + 405h^2r_{n+2} + 405h^2r_{n+1} + 135h^2r_{n+3} \]
\[ + 135h^2r_{n+2} - 360y_{n+2}) \] (10)

The values of \( r \) is taken in the interval \( r \in (2,3) \) to obtain a particular discrete hybrid method. For the purpose of testing the properties of equation (9), the value of \( r \) is taken to be \( \frac{5}{2} \) to have

\[ y_{n+3} = 2y_{n+2} - y_{n+2} + \frac{h^2}{384}(33f_{n+3} + 83f_{n+2} - 25f_{n+1} + 5f_n) \] (11)

with its first derivative given by

\[ hy_{n+3}' = 2y_{n+2} - 2y_{n+2} + \frac{h}{5760}(2047f_{n+3} \]
\[ + 3069f_{n+2} - 999f_{n+1} + 203f_n) \] (12)

3. Implementation of the Method (11)

In order to implement the implicit linear one-point discrete scheme (11) and its derivative (12), the symmetric explicit schemes and their derivatives are also developed by the same procedure for the construction of \( y_{n+3} \) and \( y_{n+3}' \) contained in \( f_{n+3} \) in the main scheme (11) and its derivative (12).

\[ y_{n+3} = 2y_{n+2} - y_{n+2} + \frac{h^2}{240}(66f_{n+3} - 10f_{n+2} + 5f_{n+1} - f_n) \] (13)

and its first derivative as

\[ hy_{n+3}' = -2hy_{n+2} + 2hy_{n+1} \]
\[ + \frac{h^2}{3600}(-4094f_{n+3} + 1920f_{n+2} - 655f_{n+1} + 129f_n) \] (14)

Other explicit schemes were also generated to evaluate other starting values using Taylor series expansions to evaluate the values for \( y_{n+i} \) and \( y'_{n+i} \) as

\[ y_{n+i} = y_n + (jh)y_n + \frac{(jh)^2}{2!}f_n + \frac{(jh)^3}{3!}y'n \frac{\partial f_n}{\partial y_n} + \frac{\partial f_n}{\partial y_n} + f_n \frac{\partial f_n}{\partial y_n'} + o(h^4) \] (15)

and

\[ y'_{n+i} = y'_n + (jh)y'_n + \frac{(jh)^2}{2!} \left( \frac{\partial f_n}{\partial x_n} + y' n \frac{\partial f_n}{\partial y_n} + f_n \frac{\partial f_n}{\partial y_n'} \right) + o(h^4) \] (16)

4. Stability Analysis

4.1. Region of Absolute Stability

In order to investigate the periodic stability properties of the numerical methods for solving the initial-value problem equation 1 and the interval of periodicity, Lambert and Watson [3] introduced the following scalar test problem as

\[ y'' = -\lambda^2y \] (17)

Based on the theory developed in Lambert and Watson [3], when multistep method

\[ \sum_{j=0}^{l} \alpha_j y_{n+j} = h^2 \sum_{j=0}^{l} \theta_j f_{n+j}, \] (18)

is applied to the scalar test equation (17), a difference equation of the form

\[ \sum_{i=0}^{l} (\alpha_i + H^2 \theta_i) y_{n+i} = 0 \] (19)

is obtained, where \( H = ph, \) \( h \) is the step length and \( y_n \) is the computed approximation to \( y(x_n + nh), \) \( n = 0, 1, 2, \ldots \)

Then, we have following definitions.

Definition. (See Konguetosof and Simos, [12]) Numerical method (19) has an interval of periodicity \((0, H_0^2), H \) if \( \forall H^2 \in (0, H_0^2), Q_i, i = 1(1)l \) satisfy

\[ |Q_1| = |Q_2| = 1, \quad |Q_j| \leq 1, \quad j = 3(1)l. \] (20)

Definition. Following [3], a numerical method is P-stable if its interval of periodicity is \((0, \infty)\). Therefore, we obtain the interval of periodicity of the new method, which is Equal to \((0, -2.4)\) and the stability domain of the method is as shown in Figure 1.

![Figure 1: The stability domain of the new method](image)

4.2. Order and Error Constant of the Method

The method proposed by Lambert (1973) in Olanegan et al. [13] is adopted in this paper, with linear operator:

\[ \sum_{j=0}^{k} \alpha_j y_{n+j} = h^2 \sum_{j=0}^{k} \beta_j f_{n+j} \] (21)
We associate the linear operator $L$ with the scheme and defined as

$$L[y(x), h] = \sum_{j=0}^{k}[\alpha_j y(x + jh) - h^2 \beta_j y''(x + jh)]$$ (22)

Where $\alpha_0$ and $\beta_0$ are both non-zero and $y(x)$ is an arbitrary function which is continuous and differentiable on the interval $[a, b]$. Expanding the form $y(x)$ and $y''(x)$ in Taylor series and comparing coefficients of $h$, we obtained

$$\Delta[y(x); h] = C_0 y(x) + C_1 h y'(x) + \cdots + C_p h^p y^p(x)$$

$$+ C_{p+1} h^{p+1} y^{p+1}(x) + C_{p+2} h^{p+2} y^{p+2}(x) + \cdots$$ (23)

The method (11) and its subordinate linear difference operator (13) are said to have order $p$ if $c_0 = c_1 = \cdots = c_{p+1} = 0$ and $c_{p+2} \neq 0$. The value $c_{p+2}$ is called error constant. Therefore, in this paper, the method (11) is of order 4 and the error constant $c_{p+2} = -\frac{21}{1536}$ or $-8.2031 \times 10^{-3}$ and its derivative (12) is of order 4 and error constant $c_{p+2} = -\frac{35}{1536}$ or $-2.2786 \times 10^{-2}$.

4.3. Consistency of the Method

A numerical method is said to be consistent if the following conditions are satisfied

1. The order of the method must be greater or equal to 1, $p \geq 1$.
2. $\sum_{j=0}^{k} \alpha_j = 0$
3. $\rho(r) = \rho'(r) = 0$
4. $\rho''(r) = 2! \sigma(r)$

Where $\rho(r)$ and $\sigma(r)$ are the first and second characteristics polynomial of our method, according to Adesanya et al. [14], the first condition is a sufficient condition for a method to be consistent. Since our method is of order 4 then it is consistent.

4.4. Zero Stability

Since $|z| = 0, 0, 1| \leq 1$ the method is zero stable.

4.5. Convergence

A method is said to be convergent if and only if it is consistent and zero stable, hence our method is convergent.

5. Numerical Examples

The method is applied to solve the following linear and nonlinear second order initial value problems of ordinary differential equations directly without reduction to system of first order equations.

Problem 1: $y'' = y', y(0) = 0; y'(0) = -1; h = 0.1$

Theoretical solution: $y(x) = 1 - e^x$

This problem has been used in Kayode and Adeyeye [8] of order six to check the behavior of the methods. Table 1 shows the absolute errors of the methods for the purpose of comparison.

The obtained results in the Table give the good performance of the proposed method.

Problem 2: $y'' + 1001y' + 1000y = 0, y(0) = 1; y'(0) = -1; h = 0.05$

Theoretical solution: $y(x) = e^{-x}$

The Problem 2 was solved by Anake [15] of order 4. The new method was applied to solve it for the purpose of comparison. The results are shown in Table 2.

Problem 3: $y'' - 100y', y(0) = 1; y'(0) = -10; h = 0.01$

Theoretical solution: $y(x) = e^{-10x}$

Table shows the absolute errors at different points of the integration interval when $h = 0.01$ was solved by Awari [16] of order five. The new method was applied to solve it for the purpose of comparison. The results show that the proposed method performed better than Awari [16].

Problem 4: $y'' - x(y')^2 = 0, y(0) = 1; y'(0) = \frac{1}{2}; h = 0.003125$

Theoretical solution: $y(x) = 1 + \frac{1}{2} \ln\left[\frac{2 + \sqrt{2}}{2 - \sqrt{2}}\right]$

We have solved this problem with the new method and the results have been compared with Kayode and Adeyeye [7] of order six shown in Table 5.

Problem 5: Resonance Vibration of a Machine

A stamping machine applies hammering forces on metal sheets by a die attached to the plunger moves vertically up and down by a fly wheel spinning at constant set speed. The constant rotational speed of the fly wheel makes the impact force on the sheet metal, and therefore the supporting base, intermittent and cyclic. The bearing base on which the metal sheet is situated has a mass, $M = 2000kg$. The force acting on the base follows a function: $F(t) = 2000 \sin(10t)$, in which $t - time$ in seconds. The base is supported by an elastic pad with an equivalent spring constant $k = 2 \times 10^5 N/m$. Determine the differential equation for the instantaneous position of the base $y(t)$ if the base is initially depressed down by an amount $0.1m$.

Solution: The mass-spring system above is modeled as differential equation as:

The Bearing base mass = $2000kg$

Spring constant $k = 2 \times 10^5 N/m$

Force ($ma$) on the metal sheet = $m \frac{dy}{dt} = my''$

i.e. $ma = my'' = 2000 \sin(10t)$; where $a = y''$. Initial conditions on the system are $y(t_0) = y_0; \frac{dy}{dt} |_{t=0} = y'_0; t_0 = 0, y'_0 = 0.1$

Therefore, the governing equation for the instantaneous position of the base $y(t)$ is given by

$My'' + ky = F(t); y(t_0) = y_0, y'(t_0) = y'_0$

$2000y'' + 2 \times 10^5 y = 2000 \sin10t, y'(0) = 0, y(0) = 0.1$

Theoretical solution: $y(t) = \frac{1}{10} \cos10t + \frac{1}{10} \sin10t - \frac{2}{10} \cos10t$

6. Conclusion

An order four continuous numerical method for solving general second order ordinary differential equations is proposed and applied to solve directly without reducing to system of first

order ordinary differential equations. The method is very flexible and easy to develop and may be applied to solve kinds of second order initial value problems as can be seen in the numerical examples. The method gives a high accuracy when compared the numerical results to the exact solution and a very good performance compared with existing methods in the literature.
